Breech baby and external cephalic version (ECV)
Breech baby at the end of pregnancy

About this information

This information is for you if your baby remains in the breech position after 36 weeks of pregnancy.

Key points

• Breech is very common in early pregnancy, and by 36 to 37 weeks of pregnancy most babies will turn into the head-first position. If your baby remains breech, it does not usually mean that you or your baby have any problems

• Turning your baby into the head-first position so that you can have a vaginal delivery is a safe option

• The alternatives to turning your baby into the head-first position are either to have a planned caesarean section or a planned vaginal breech birth.

Date of ECV ................................. Time of ECV ............................

Please ring ext 5163 on the morning of ECV at ......................... to confirm admission time.
What is breech?

Babies lying bottom first or feet first in the uterus (womb) instead of in the usual head-first position are called breech babies. Breech is very common in early pregnancy, and by 36 to 37 weeks of pregnancy, most babies turn naturally into the head-first position.

Towards the end of pregnancy, only three to 4 in every 100 (three to four per cent) babies are in the breech position.

A breech baby may be lying in one of the following positions:

- Extended or frank breech – the baby is bottom first, with the thighs against the chest and feet up by the ears. Most breech babies are in this position
- Flexed or complete breech – the baby is bottom first, with the thighs against the chest and the knees bent
- Footling breech – the baby’s foot or feet are below the bottom.

Why is my baby breech?

It may just be a matter of chance that your baby has not turned into the head-first position. However, there are certain factors that make it more difficult for your baby to turn during pregnancy and therefore more likely to stay in the breech position.
These include:

• If this is your first pregnancy

• If your placenta is in a low-lying position (also known as placenta praevia); see the RCOG patient information *A low-lying placenta (placenta praevia) after 20 weeks*, which is available at: [www.rcog.org.uk/en/patients/patient-leaflets/a-low-lying-placenta-after-20-weeks-placenta-praevia/](http://www.rcog.org.uk/en/patients/patient-leaflets/a-low-lying-placenta-after-20-weeks-placenta-praevia/)

• If you have too much or too little fluid (amniotic fluid) around your baby

• If you are having more than one baby

• Your womb is an unusual shape.

Very rarely, breech may be a sign of a problem with the baby. If this is the case, such problems may be picked up during the scan you are offered at around 20 weeks of pregnancy. The vast majority of breech babies are healthy when they are born. However, for a few babies, being breech may be a sign that there is a problem. All babies will have a newborn examination before they leave the maternity unit to check if there are any problems.
What if my baby is breech towards the end of my pregnancy?

If your baby is breech at 36 weeks of pregnancy, your healthcare professional will discuss the following options with you:

- Trying to turn your baby in the uterus into the head-first position by external cephalic version (ECV)
- planned caesarean section
- planned vaginal breech birth.

External cephalic version (ECV) – turning a breech baby in the uterus

What does ECV involve?

ECV involves applying gentle but firm pressure on your abdomen to help your baby turn in the uterus to lie head-first.

Relaxing the muscle of your uterus with medication has been shown to improve the chances of turning your baby. This medication is given by injection before the ECV and is safe for both you and your baby. It may make you feel flushed and you may become aware of your heart beating faster than usual but this will only be for a short time.

Before the ECV you will have an ultrasound scan to confirm your baby is breech, and your pulse and blood pressure will be checked. You will be asked to sign a consent form prior to the procedure. After the ECV, the ultrasound scan will be repeated to see whether your baby has turned. Your baby’s heart rate
will also be monitored before and after the procedure. You will be advised to contact the hospital if you have any bleeding, abdominal pain, contractions or reduced fetal movements after ECV.

ECV is usually performed after 36 weeks of pregnancy. However, it can be performed right up until the early stages of labour. You do not need to make any preparations for your ECV. The procedure itself lasts about ten minutes.

ECV can be uncomfortable and occasionally painful but your healthcare professional will stop if you are experiencing pain and the procedure will only last for a few minutes. If your healthcare professional is unsuccessful at their first attempt in turning your baby then, with your consent, they may try again on another day.

If your blood type is rhesus D negative, you will be advised to have an anti-D injection after the ECV and to have a blood test. See the NICE patient information *Routine antenatal anti-D prophylaxis for women who are rhesus D negative*, which is available at: www.nice.org.uk/guidance/ta156/informationforpublic

**Why turn my baby head-first?**

If your ECV is successful and your baby is turned into the head-first position you are more likely to have a vaginal birth. Successful ECV lowers your chances of requiring a caesarean section and its associated risks.
Is ECV safe for me and my baby?

ECV is generally safe with a very low complication rate. Overall, there does not appear to be an increased risk to your baby from having ECV. After ECV has been performed, you will normally be able to go home on the same day.

When you do go into labour, your chances of needing an emergency caesarean section, forceps or vacuum (suction cup) birth is slightly higher than if your baby had always been in a head-down position.

ECV should be carried out by a doctor or a midwife trained in ECV. It should be carried out in a hospital where you can have an emergency caesarean section if needed. Immediately after ECV, there is a 1 in 200 chance of you needing an emergency caesarean section because of bleeding from the placenta and/or changes in your baby’s heartbeat.

ECV can be carried out on most women, even if they have had one caesarean section before.

What should I look for after ECV?

If you have bleeding, abdominal pain, contractions or your baby’s movements are reduced after ECV you should telephone the maternity unit on 01702 385301 or 01702 385486.
ECV should not be carried out if:

- You need a caesarean section for other reasons, such as placenta praevia; see the RCOG patient information *A low-lying placenta (placenta praevia) after 20 weeks*, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/a-low-lying-placenta-after-20-weeks-placenta-praevia

- You have had recent vaginal bleeding during the last seven days

- Your baby’s heart rate tracing (also known as CTG) is abnormal

- Your waters have broken

- You are pregnant with more than one baby; see the RCOG patient information *Multiple pregnancy: having more than one baby*, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/multiple-pregnancy-having-more-than-one-baby/. However it may be performed if during delivery your last baby is breech or not in the correct position.

Is ECV always successful?

ECV is successful for about fifty per cent of women. It is more likely to work if you have had a vaginal birth before. Your healthcare team should give you information about the chances of your baby turning based on their assessment of your pregnancy.

If your baby does not turn then your healthcare professional will discuss your options of performing the procedure under regional (spinal) anaesthesia. It is possible to have another attempt at ECV on a different day.
If ECV is successful, there is still a small chance that your baby will turn back to the breech position. However, this happens to less than 5 in 100 (five per cent) women who have had a successful ECV.

Is there anything else I can do to help my baby turn?

There is no scientific evidence that lying down or sitting in a particular position can help your baby to turn. There is some evidence that the use of moxibustion (burning a Chinese herb called mugwort) at 33 to 35 weeks of pregnancy may help your baby to turn into the head-first position, possibly by encouraging your baby’s movements. This should be performed under the direction of a registered healthcare practitioner.

What are my options for birth if my baby remains breech?

Depending on your situation, your choices are:

• planned caesarean section

• planned vaginal breech birth.

There are benefits and risks associated with both caesarean section and vaginal breech birth, and these should be discussed with you so that you can choose what is best for you and your baby.
Caesarean section

If your baby remains breech towards the end of pregnancy, you should be given the option of a caesarean section. Research has shown that planned caesarean section is safer for your baby than a vaginal breech birth. Caesarean section carries slightly more risk for you than a vaginal birth.

Caesarean section can increase your chances of problems in future pregnancies. These may include placental problems, difficulty with repeat caesarean section surgery and a small increase in stillbirth in subsequent pregnancies. See the RCOG patient information Choosing to have a caesarean section, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/choosing-to-have-a-caesarean-section/

If you choose to have a caesarean section but then go into labour before your planned operation, your healthcare professional will examine you to assess whether it is safe to go ahead. If the baby is close to being born, it may be safer for you to have a vaginal breech birth.

Vaginal breech birth

After discussion with your healthcare professional about you and your baby’s suitability for a breech delivery, you may choose to have a vaginal breech birth. If you choose this option, you will need to be cared for by a team trained in helping women to have breech babies vaginally. You should plan a hospital birth where you can have an emergency caesarean section if needed, as 4 in 10 (forty per cent) women planning a vaginal breech birth do need a caesarean section. Induction of labour is not usually recommended.
While a successful vaginal birth carries the least risks for you, it carries a small increased risk of your baby dying around the time of delivery. A vaginal breech birth may also cause serious short-term complications for your baby. However, these complications do not seem to have any long-term effects on your baby. Your individual risks should be discussed with you by your healthcare team.

Before choosing a vaginal breech birth, it is advised that you and your baby are assessed by your healthcare professional. They may advise against a vaginal birth if:

- Your baby is a footling breech (one or both of the baby’s feet are below its bottom)
- Your baby is larger or smaller than average (your healthcare team will discuss this with you)
- Your baby is in a certain position, for example, if its neck is very tilted back (hyper extended)
- You have a low-lying placenta (placenta praevia); see the RCOG patient information A low-lying placenta (placenta praevia) after 20 weeks, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/a-low-lying-placenta-after-20-weeks-placenta-praevia/
- You have pre-eclampsia or any other pregnancy problems; see the RCOG patient information Pre-eclampsia, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/pre-eclampsia/
What can I expect in labour with a breech baby?

With a breech baby you have the same choices for pain relief as with a baby who is in the head-first position. If you choose to have an epidural, there is an increased chance of a caesarean section. However, whatever you choose, a calm atmosphere with continuous support should be provided.

If you have a vaginal breech birth, your baby’s heart rate will usually be monitored continuously as this has been shown to improve your baby’s chance of a good outcome.

In some circumstances, for example, if there are concerns about your baby’s heart rate or if your labour is not progressing, you may need an emergency caesarean section during labour. A paediatrician (a doctor who specialises in the care of babies, children and teenagers) will attend the birth to check your baby is doing well.

What if I go into labour early?

If you go into labour before 37 weeks of pregnancy, the balance of the benefits and risks of having a caesarean section or vaginal birth changes and will be discussed with you.

What if I am having more than one baby and one of them is breech?

If you are having twins and the first baby is breech, your healthcare professional will usually recommend a planned caesarean section.
If, however, the first baby is head-first, the position of the second baby is less important. This is because, after the birth of the first baby, the second baby has lots more room to move. It may turn naturally into a head-first position or a doctor may be able to help the baby to turn. See the RCOG patient information *Multiple pregnancy: having more than one baby*, which is available at: www.rcog.org.uk/en/patients/patient-leaflets/multiple-pregnancy-having-more-than-one-baby/

If you would like further information on breech babies and breech birth, you should speak with your healthcare professional.
